

What is a microgrid control system?

Without the inertia associated with electrical machines, a power system frequency can change instantaneously, thus tripping off power sources and loads and causing a blackout. Microgrid control systems (MGCSs) are used to address these fundamental problems. The primary role of an MGCS is to improve grid resiliency.

Can a microgrid enable automatic energy transaction with the main grid?

Researchers in [1] have proposed two energy management algorithms for a microgrid to enable automatic energy transaction with the main grid. The first algorithm involves MPC with linear programming to efficiently predict the energy generation, demand and prices.

Do microgrids have problems?

These grids commonly include a high percentage of renewable energy power supplies, such as photovoltaic (PV) and wind generation. Microgrids, therefore, commonly have problems related to their low system inertia and the intrinsic limitations of power electronic sources (PESs).

How to manage power in a microgrid?

The optimal power management for the entire microgrid is managed by linear programming which tracks the reference power from all the neural controllers. However, different variable conditions like wind speed, SoC etc. are not analysed in the paper.

Should microgrids be controlled?

While it has been a common notion that microgrids are preferable to solve local problems and can support the pathway to decarbonise and self-healing grid of the future, control and management of DERs will remain the area of exploration.

Are traditional control techniques enough to support dynamic microgrid environments?

Integration, coordination and control of multiple DERs and managing the energy transition in this environment is a strenuous task. Classical control techniques are not enough to support dynamic microgrid environments.
